AB This invention relates to an expression cassette for expressing polypeptides in eukaryotic cells using alternative splicing. An expression vector that uses a single promoter to drive transcription of an mRNA encoding two components of a heterooligomeric protein is described. Downstream of the promoter is a 5'-untranslated region, a donor splice site, an intron, and an acceptor splice site. This is followed by the coding region for one of the proteins of the complex and a second acceptor splice site. Immediately downstream of this is the coding region for the second protein, and an internal ribosome entry site (IRES.). The IRES is adjacent to a selectable marker gene that is transcribed from the same promoter. The 3'-end of the expression cassette includes a 3'-untranslated region with a unique polyadenylation signal. Selection of splice acceptor sites to give different ratios of the upstream and downstream gene products is demonstrated for CHO, HeLa, and 3T3 cells.

AB Reporter gene vectors that can be used to identify genes expressed during cell differentiation are described. The vectors use a promoterless gene for a recombinase and a reporter gene, typically for a green fluorescent protein, under control of a promoter specific for a cell type. The recombinase gene is flanked by sites that will block expression of the reporter gene as long as the intact vector is integrated into the genome. The vector is integrated randomly into the host cell genome. If the recombinase gene integrates at a site where it is under the control of a promoter regulated by cell differentiation, then expression of the recombinase gene upon differentiation will lead to its excision. This results in expression of the reporter gene when the cells reach the stage at which the promoter regulating it is used. The reporter gene also acts as a label for identification of the promoter. If a gene for a fluorescent protein is used, then these cells can be selected by fluorescence-activated cell sorting.
